

MONAD × X402 · HACKATHON SUBMISSION

Continuous Clearing Auction

A token launch that discovers its own price. Bidders sign capped demand curves off-chain; only the fills touch Monad.

219

bids signed

54

on-chain transactions

120/120

units cleared

1.455

USDC raised, Monad testnet

THE PROBLEM

Today's launchpads set a price before demand is known

	PUMP.FUN CURVE	UNISWAP LP RATIO	THIS AUCTION
Who sets the price	A hard-coded curve	Whoever seeds the pool	The order book
Who gets the supply	Fastest bot in block one	Whoever swaps first	Every bid above clearing, pro-rata at it
What a losing bid costs	Gas, slippage, a bad entry	Gas, and the sandwich	Nothing. No fee, no gas, no state
Reward for bidding early	Speed, not conviction	Speed, not conviction	A lower blended price than the marginal buyer

PRICE DISCOVERY

The auction removes the guess

PRICE GUESSED	UNITS SOLD	REVENUE
0.005	120	0.600
0.013	120	1.560
0.016	102	1.632
0.020	36	0.720
auction	120	1.455

1.26×

the average guess

2.42×

the worst guess

It concedes 11% to the best guess — an oracle that only exists afterwards.

THE PRIMITIVE

x402 upto is already an auction

Authorize a maximum, settle for less. Documented as metering for API calls; read as a bid, the whole mechanism falls out of the settlement rule.

UPTO MECHANIC

Signed maximum

Settle $\leq$ max

\$0 settlement, no tx

Witness binds to

Permit2 nonce

AUCTION MEANING

The bid

Uniform clearing price — you pay less than you bid

Losing bids are free

Proceeds cannot be redirected

A bid cannot be replayed

FAIR ALLOCATION

Everyone who fills pays the same price

BIDDER	CEILING	CHARGED	UNSPENT
tony.monad	0.040	0.022	0.018
intrepid.monad	0.036	0.022	0.014
dragon.monad	0.032	0.022	0.010
whale.monad	0.013	0.011	0.002

Block 1, settled on Monad testnet. Rungs above the clearing price fill completely; rungs at it share the remainder pro-rata.

0.623

USDC signed for and never taken

Buyer surplus is the gap between the ceiling and the uniform price. It is enforced on-chain by the proxy, not promised.

WHY MONAD

Continuous clearing needs blocks this fast

~40x

**finer clearing than
Ethereum**

12s blocks make CCA continuous in name only. At ~0.3s a round completes in ~0.6s wall clock.

219→54

bids to transactions

Cost scales with winners, not bidders. Bidding is free; on Uniswap's on-chain CCA, placing a bid is a transaction.

0 gas

paid by any bidder

The facilitator sends every settlement. A bidder needs USDC and one lifetime Permit2 approval.

A bidder filled across five ticks means five transfers — prohibitive on Ethereum, noise on Monad.

THE RUN

13 blocks, 51 settlements, no failures

0.013
final clearing

1.560
implied MC

DON'T TRUST IT — CHECK IT

Every price re-derives from the published bid set

219/219 signatures

Winners and losers, recovered by
ecrecover from rebuilt EIP-712 digests.

58/58 settlements

Confirmed by direct receipt lookup
against Monad RPC. No indexer in
the path.

Hash-chained rounds

A fabricated losing bid fails twice: the
price stops re-deriving and the
signature stops recovering.

```
$ python3 server.py → localhost:8080  
$ python3 verify_proof.py --onchain --sigs
```
